

SLC26A2 Recessive multiple epiphyseal dysplasia affects males and females in equal numbers. The exact incidence or prevalence of the disorder is unknown, but multiple epiphyseal dysplasia, collectively, has been estimated to occur in approximately 1 in 20,000 people in the general population. rMED is estimated to account for approximately 25% of all cases of multiple epiphyseal dysplasia. Because some cases go undiagnosed or misdiagnosed, determining the true frequency these disorders in the general population is difficult.
